INTRODUCTION

Since it has been the primary energy source since the middle of the 1950s, oil is one of the most important raw resources in the world. One of the most important sectors of the world economy, the oil business has a big influence on how other industries grow. In addition to being employed in modern medicine, this energy source powers automobiles, generates electricity for water and home heating, and is necessary for the manufacture of domestic cleaning goods. The global economy is mostly driven by the oil and gas sector, which also supports numerous other important businesses including manufacturing and the automobile industry.

The competitiveness of enterprises in the oil industry is constantly impacted by technological breakthroughs, market volatility, and evolving client expectations. As a result, strategic and tactical restructuring is vital. The industry's main concern right now is cutting production costs and the time it takes to get finished goods to customers. Increasing the productivity and competitiveness of petrochemical facilities and their supply chains as a whole requires effective supply chain management. A supply chain facilitates the transfer of capital, information, and materials by connecting a business with its downstream distributors and upstream suppliers.

The purpose of this essay is to examine why supply chain management is important for the oil and gas sector. The article centres on the oil business, specifically highlighting the supply chain management systems that operate inside it.

ARTICLE OBJECTIVES

1. The Oil Industry's Supply Chain and the Need for Supply Chain Management System Implementation

¹ How to cite the article: Mudunuri L.N.R.; Utilizing AI for Cost Optimization in Maintenance Supply Management within the Oil Industry; *International Journal of Innovations in Applied Sciences and Engineering*; Special Issue 1 (2024), Vol 10, No. 1, 10-18

The entire process of oil product discovery, extraction, refinement, distribution, and delivery is included in the oil industry's logistic chain. This chain consists of three stages: production and exploration upstream, transportation and storage midstream, and consumer distribution and refining downstream. The optimisation of operations, cost reduction, and efficiency improvement are the driving forces behind the implementation of a supply chain management (SCM) system in the oil business. SCM that is effective addresses the particular complexities and difficulties faced by the oil sector while ensuring the smooth transfer of supplies, data, and funds from suppliers to end users.

2. An Overview of the SCM System and Its Potential

To simplify operations, a supply chain management system combines many processes including order fulfilment, inventory control, logistics, and procurement. An SCM system provides chances for better coordination among many stakeholders, increased visibility throughout the supply chain, and data-driven decision-making in the oil business. SCM systems can effectively manage inventory levels, estimate demand, and follow the movement of oil products in real time by utilising technology. Lead times are shortened, distribution expenses are kept to a minimum, and there is a steady supply of crude oil and its derivatives thanks to this integration.

3. The Oil Industry's Efficiency in Using the SCM System

The oil sector may greatly increase efficiency by putting in place a supply chain management system. Good supply chain management (SCM) techniques improve inventory control, which minimises the need for unnecessary stockpiling and storage expenses. Reducing fuel usage and transit times through better logistics and transportation management can further reduce expenses. Improved cooperation between distributors and suppliers can result in further strategic alliances, which can stimulate creativity and cooperative solutions to shared problems. In his paper "Supply Chain Management in the Petroleum Industry: Challenges and Opportunities," Raed Husain claims that maintaining steady supplies of crude oil, cutting lead times, and lowering distribution costs all depend on more effective and economical supply chain procedures.

Despite the challenges, opportunities for improvements and cost savings exist throughout the supply chain. Husain also highlights the potential for systematic cooperative reciprocal barter, or swaps, where companies collaborate with competitors to find shared solutions, offering significant savings and new opportunities.

Christopher M. Chima, in his article "Supply-Chain Management Issues in the Oil and Gas Industry," discusses the global nature of the oil industry's supply chain, which includes domestic and international transportation, ordering and inventory visibility and control, materials handling, and information technology. Chima illustrates how the oil industry provides a classic model for implementing SCM techniques, emphasizing the role of supply-chain logistics in improving overall efficiency.

METHODOLOGY

It's useful to divide the business system into a value chain—a collection of value-generating activities—in order to have a better understanding of how a company builds competitive advantage and generates shareholder value (Porter, 2004). The value chain, which comprises of margin and value operations, shows overall value. Value activities are the specific technological and physical tasks a business completes to produce goods that are useful to its clients. The difference between the overall value and the total cost of carrying out these value-adding activities is represented by the margin. The processes involved in producing a good or service, adding value as well as cost, are examined using Porter's value chain model.

Depending on whether they are auxiliary or fundamental company tasks, these activities are categorised as primary or secondary. Offering clients a level of value that surpasses the expense of these endeavours is the aim in order to generate a profit margin.

Primary activities can be broadly classified into five areas: inbound logistics, operations, outbound logistics, marketing and sales, and service. Primary activities, according to Porter (1985), are directly involved in the creation or delivery of a product or service.

Porter Five Forces Analysis

1. Barriers to Entry

The ease with which new companies can enter an industry affects the level of competition. Barriers to entry are factors that can limit the threat of new entrants. The oil and oil services industry, despite having thousands of companies worldwide, presents significant obstacles that deter all but the most serious entrants. These barriers vary by market segment. For example, certain types of pumping vehicles needed at well sites can cost over \$1 million each. Additionally, some areas of the oil business require highly specialized workers to operate equipment and make critical drilling decisions. Companies involved in such specialized sectors face higher barriers to entry than those offering general drilling or support services. Furthermore, substantial financial resources are necessary to compete with established oil companies, making sufficient capital another significant barrier to entry.

2. Supplier Power

Supplier power refers to the pressure suppliers can exert on a business. If a supplier can significantly influence a company's margins and quantities, it wields substantial power. In the oil industry, despite the presence of numerous companies, the market is dominated by a few powerful firms. The significant capital investment required for rigs, pipelines, and refining equipment limits the number of suppliers in these areas. Although competition among these suppliers is not highly intense, they hold considerable power over smaller drilling and support companies.

3. Buyer Power

Buyer power is the pressure customers can exert on a business. If a customer can significantly impact a company's margins and quantities, they possess considerable power. The balance of power in the oil industry is shifting towards buyers. Since oil is a commodity and one company's oil or drilling services are not significantly different from another's, customers are driven to seek lower prices and better contract terms.

4. Availability of Substitutes

The availability of substitutes measures the likelihood of customers switching to a competing product or service. If the cost of switching is low, this poses a serious threat. Several factors influence the risk of substitutes, primarily the similarity of the alternatives. In the oil industry, substitutes include alternative fuels such as coal, natural gas, solar power, wind energy, hydroelectricity, and nuclear energy. Since oil is used for more than just powering vehicles, including in plastics and other materials, the threat from substitutes varies depending on the specific area in which a company operates. Companies providing specialized services, such as seismic drilling or directional drilling tools, are less vulnerable to the threat of substitutes.

5. Competitive Rivalry

Competitive rivalry refers to the intensity of competition among existing companies within an industry. Highly competitive sectors often experience low returns due to the high costs associated with competition. Factors contributing to intense competition include the presence of many similarly sized players, the absence of a dominant firm, and minimal differentiation between competitors' products and services.

Michael Porter's Five Forces model is invaluable for evaluating the oil industry. A strategic business manager can use this model to gain a better understanding of the industry's context and develop an advantage over rival businesses.

NECESSITY OF THE SUPPLY-CHAIN MANAGEMENT IN THE OIL INDUSTRY

The steadily increasing global demand for oil and its derivatives, such as petrochemicals, has enabled companies providing these products to reach more customers, thereby increasing their market share and profitability. This surge in global demand, coupled with the ease of international trade and the inherent inflexibility of the petroleum industry's supply chain, has made its management more complex and challenging. Despite the critical importance and growing complexity of supply chain management, the petroleum industry is still in the early stages of effectively managing its supply chains. According to Steve Welsh, managing director of the College of Petroleum and Energy Studies at the University of Oxford, the oil and petrochemical industry's understanding of supply chain management is still in its

infancy. However, even with the inflexibility and complexity of the industry's supply chain, there is considerable potential for improvement and cost reduction, particularly in logistics. Werner Paratorius, president of BASF's petrochemicals division, stated, "Supply chain management is the backbone of a business where logistics costs can be greater than manufacturing costs."

The supply of petroleum products to consumers is crucial, as it affects the economic health of key industries, agriculture, and the general population. The large volumes of resources used, the wide range of petroleum products, and the complexity and breadth of communications underscore the importance of coordinating procurement, storage, and supply. Additionally, tracking product movement, ensuring delivery quality, and planning transportation while considering the necessary funding are all vital components of an effective supply chain management system in the petroleum industry.

In recent times, concerns have been raised, and many have argued that the oil and gas industry may have entered an era of very scarce resources. In reality, however, resource scarcity is not the cause of supply constraints. The enormous potential still available includes currently known and booked reserves, the increasing scope for recovery from existing fields with new technologies, further potential discoveries, and the new frontier of vast oil sands and oil shale reserves that are profitable at today's prices.

According to a significant portion of industry research, there are enough resources left to sustain current production levels for at least the next 50 years. Therefore, the primary challenge facing the oil and gas industry is not the availability of resources but rather bringing these reserves into production and delivering the final products to consumers at the lowest possible cost. A robust supply chain management program will be essential in achieving this goal.

Due to the global nature of the oil industry, commodities such as oil, gas, and petrochemicals require specific transportation modes, including pipelines, vessels, tankers, and railroads. These commodities are produced in specific, limited regions of the world but are demanded globally as they represent an essential source of energy and raw material for many other industries. It is common for several weeks of lead time to elapse from the shipping point to the final customer's location. For example, it takes five weeks for oil from the Persian Gulf to reach the United States and up to another three weeks for it to be processed and delivered (Schwartz, 2000).

The great distances between supply chain partners introduce high variability in transportation times, which can negatively impact suppliers in terms of service levels and final customers in terms of safety stock costs. Additionally, as the transportation process often involves multiple modes—ships, trucks, pipelines, or railroads—a shipment may need to utilize several transportation methods before reaching its final destination.

Constraints on transportation modes in the oil industry result in long lead times from the shipping point to the final customer's location, unlike other industries. Given the inflexibility involved, meeting the growing demand for oil and its derivatives while maintaining high service levels and efficiency is a major challenge.

Opening new production sites or distribution centers closer to dispersed customers is one way to reduce lead time and transportation costs. However, acquiring such facilities in the oil and petrochemical industries is typically very costly and often leads to higher inventory and operating costs (Hebert, 2004). Red Cavaney, president of the American Petroleum Institute, stated, "Most companies are unlikely to undertake the significant investment needed to even begin the process" (Hebert, 2004). These factors are pushing oil and petrochemical companies to either absorb the increased costs or pass them on to customers, who are already facing rising prices.

Consequently, companies recognize that improving supply chain efficiencies is a significant area for cost savings, particularly in logistics. They understand that competition arises from the supply chain in which they participate as customers and suppliers, rather than from individual companies.

Key factors for reducing costs and increasing profits in managing supply chains include demand management, efficient distribution of petroleum products, better transportation scheduling, warehouse management, and the quality and timeliness of information. The true effectiveness of supply chain management lies in managing these factors as an integrated process, achievable through supply chain automation.

FEATURES OF LOGISTICS AND SCM IN THE OIL INDUSTRY

Logistics encompasses the science of transport planning, management, and control. This includes warehousing and all types of intangible and material operations that occur before goods or resources are delivered to their desired location. This process involves various logistical operations related to warehousing, inventory management, transportation, and personnel management. Essentially, logistics is crucial for effectively managing material flows.

Supply chain logistics software, or supply chain management (SCM) software, is highly valuable to operational managers. The purpose of these logistics platforms is to maximize customer value while achieving a sustainable competitive advantage. These tools support efficient transportation, warehousing, inventory management, and logistics network design to seamlessly link the flow of products, data, and finances. Most organizations today rely on a robust SCM solution. Here are the essential features of a solid software platform.

Improving efficiency and competitiveness requires reducing costs associated with oil production and refining. Operations in mining and processing also involve stringent safety and environmental requirements. Therefore, organizing logistics in the oil and gas industry demands a specialized approach to building the supply chain. The movement of goods from the initial to the endpoint must be strictly controlled to reduce costs, which arise at all stages of material flow—procurement, transportation, storage, and distribution to end users. Logistics involves an integrated approach to identifying and reducing costs across all logistical links, from supply to distribution.

In today's competitive market, logistics serves as a strategic weapon, enhancing the efficiency of enterprises, optimizing resource potential, and expanding areas for finding reserves outside production. The oil and gas industry encompasses various sectors involved in supply, transportation, storage, and distribution, dealing with materials in gaseous, liquid, and solid phases.

The implementation of logistics aims to reduce time losses in the production cycle, minimize order and inventory times, enhance innovation processes, and ensure compliance with contractual obligations. It also strengthens the integration of all material flows in the production process. To effectively manage logistics, a robust operational communication system is essential, reflecting the movement of material flows from the contract with a supplier to the final consumption of the product.

Logistic activities utilize warehouses or transshipment facilities to create logistic networks, enabling the regional consolidation of transports for different customers and suppliers. Freight consolidation increases transportation efficiency and reduces overall transportation distance and CO₂ emissions.

To achieve high customer service delivery and performance results, a sophisticated supply chain is necessary. This chain must facilitate the smooth flow of information, goods, and services, both inbound and outbound. The main objective of supply chain management (SCM) is to boost sales, minimize costs, and maximize business assets by enhancing collaboration and communication among all supply chain participants. SCM integrates all participants and coordinates the basic flows of products, services, information, and funds. This interdependence among firms leads to increased trade in transitional goods or services, technical know-how, and production networks, resulting in clear business gains.

THE OIL SUPPLY CHAIN

According to Christopher M. Chima, "Supply chain management in the petroleum industry involves the configuration, coordination, and continuous improvement of sequentially organized operations across upstream, midstream, and downstream segments" [2]. The oil supply chain is divided into three functional segments: Upstream, Midstream, and Downstream (Fig. 1).

In business terms, "upstream" and "downstream" describe a company's position within the supply chain. The further a function or company is from the end user, the more upstream it is considered. Upstream activities include raw material extraction or production. These companies, often referred to as exploration and production firms, focus on identifying oil and natural gas deposits and extracting these resources from underground. Conversely, downstream elements of the supply chain involve refining and other processes closer to the final consumer.

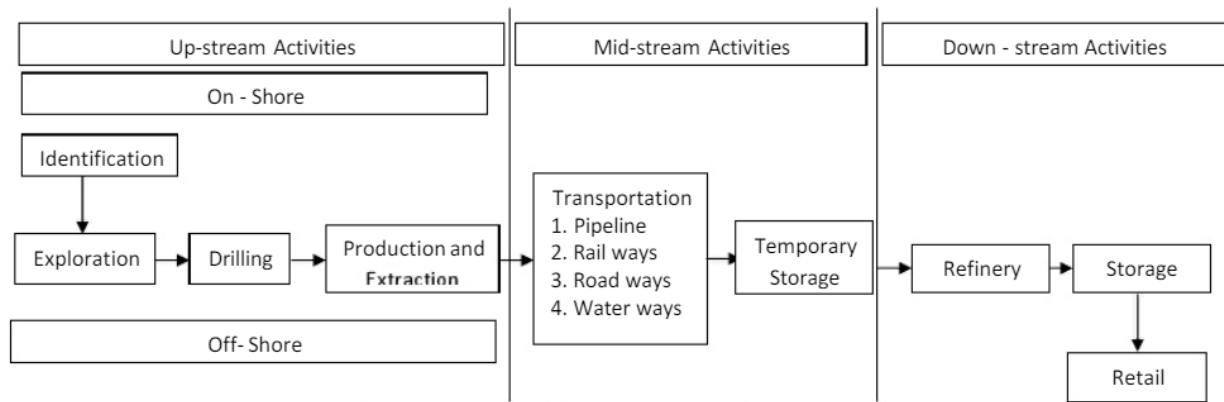

Fig. 1. Various Segments of Oil Supply Chain [9].

The upstream segment of the oil and gas industry, also known as the exploration and production (E&P) sector, involves activities related to searching for, recovering, and producing crude oil and natural gas. This sector encompasses identifying deposits, drilling wells, and extracting raw materials from underground sources. It also includes related services such as rig operations, feasibility studies, machinery rental, and supply of extraction chemicals. Key activities in the upstream segment include:

- Exploration: Conducting aerial surveys, seismic studies, geophysical and geological operations.
- Appraisal Drilling: Drilling of wildcat wells and test wells to evaluate potential deposits.
- Production and Extraction: Extracting crude oil and natural gas from identified reserves.
- Decommissioning and Rehabilitation: Managing the closure of wells and restoring the environment.

The upstream oil segment focuses on wells: determining optimal locations, depths, and drilling distances; and designing, constructing, operating, and managing them to maximize returns on investment while minimizing operational footprint and ensuring safety.

Midstream operations involve the infrastructure required for transporting crude oil and petroleum products. Positioned between the upstream and downstream segments, the midstream sector includes facilities and processes for the processing, storage, and transportation of crude oil and natural gas.

Oil and gas reserves are often geographically distant from refining assets and major consumption regions. Consequently, transportation is a key aspect of midstream activities and can involve pipelines, trucking fleets, tanker ships, and rail cars.

The core focus of the midstream sector is the gathering system, which stores hydrocarbons from the oil field until they can be transported to refineries for processing into marketable products. Midstream activities primarily include:

- Transportation
- Storage

The downstream segment of the oil and gas industry is focused on processing, transporting, and selling refined products derived from crude oil. This sector delivers a wide range of products to end-users globally. Common products include gasoline, diesel, jet fuel, heating oil, and asphalt. Additionally, it provides less familiar items such as lubricants, synthetic rubber, plastics, fertilizers, and pesticides.

Downstream operations are margin-driven, where margin is defined as the difference between the price obtained for refined products and the cost of the crude oil delivered to the refinery. This segment includes refineries, which convert

crude oil into usable products like gasoline and fuel oils, and marketing services that facilitate the distribution of these products from energy companies to retailers or end users.

Key downstream activities are:

- Refining and Processing: Transforming crude oil and gas into refined products.
- Supply and Trading: Managing the supply chain and trading of refined products.
- Marketing and Distribution: Moving finished products to retailers and end users.

Considering the structure of the oil industry, it is evident that it is complex and requires meticulous control and planning, encompassing:

1. Timely Availability of Accurate Information: Ensuring stakeholders receive the right information at the right time.
2. Integration with Vendors and Suppliers: Connecting the supply chain with vendors and suppliers for each organization involved in the process.
3. Enterprise Business Solutions: Utilizing solutions to manage multi-modal transportation, resource tracking, logistics, and cost management.
4. Access to Customized IT Solutions: Leveraging both new customized IT solutions and off-the-shelf options from vendors.
5. Market Demand and Supply Analysis: Assessing market demand and supply to provide products that best meet customer needs.
6. Delivery Planning: Strategically planning deliveries to prevent excess inventory or unmet demand.

Information technology is crucial for maintaining a seamless information flow in the complex supply management of the oil industry. To optimize the petroleum supply system, it is essential to consider all links in the logistics chain, from oil refineries to commercial intermediaries, and ultimately to the end consumers. Building a network of effective communication among producers, trading firms, intermediaries, and financial structures is key, with logistics companies serving as a central unifying element.

Supply Chain Management (SCM) aims to create a sales network where goods are delivered to the right place at the right time with minimal cost. This concept focuses on:

- Analyzing market demand and supply to align products with customer needs.- Efficiently processing orders and requests.
 - Planning deliveries to avoid inventory shortages or surplus.
 - establish enduring connections with distributors and consistently broaden the sales network.
- The configuration, coordination, and ongoing improvement of a set of sequentially ordered operations is known as supply-chain management, or SCM. Supply-chain management seeks to deliver the best possible customer service at the lowest feasible cost. Anybody who uses a process's output is considered a customer. For every business that prioritises providing excellent customer service, the customer's client is crucial. Thanks to advancements in information systems and communication technology, there are now more options to coordinate activities across a supply chain, especially in complicated businesses like the oil industry. All functions can participate in supply-chain management choices by integrating operations management with other operations functions [11].

In order to provide a specific segment with the fundamental level of customer service, effective supply chain management (SCM) will increase product availability and decrease order cycle times; foster relationships with downstream supply chain partners to create value for end users and optimise benefits and minimise costs along the

supply chain; and engage in information exchange (forecasting techniques, inventory management, delivery, and just-in-time systems, outsourcing, vendor-managed inventory, and co-locating plants). As a result, participating businesses are able to observe the nature of SCM in action as it is successfully implemented in the dynamic global business environment. There are several risks, which have a significant impact on how business management makes decisions [7].

The biggest research firms, AMR Research and Forrester Research, claim that the SCM company gives them the following competitive advantages:

Profits increased from 5% to 15%; order processing costs and times shortened from 20% to 40%; market entry times shortened from 15% to 30%; procurement expenses lowered from 5% to 15%; warehouse stock levels lowered from 20% to 40%; and production expenses lowered from 5% to 15% [12].

For instance, Toyota gains numerous advantages from its enhanced supply network. Thus, compared to stocking levels in the 1980s, inventory levels at parts distribution centres have dropped by 53%.

CONCLUSION

The oil business is currently one of the most prominent and vital sectors of the economy, as the article demonstrated. The oil industry is worldwide, and certain types of transportation, such pipelines, tankers, and trains, are needed to carry goods like oil and petrochemicals. Although these goods are only produced in a few, restricted areas of the world, there is a global demand for them since they are a vital source of energy and raw materials for numerous other businesses. The primary obstacle confronting the oil industry is not the scarcity of oil reserves; rather, it is the utilisation of these reserves for production and the economical delivery of end goods to customers.

The article addressed the issue of logistics procedures in the oil industry and identified several critical elements that can lower expenses and boost profits in supply chain management. These elements include demand management, effective customer distribution of petroleum products, improved transportation scheduling, warehouse management, and timely and high-quality information. The true efficacy of supply chain management, however, is in managing these variables collectively rather than independently, which is made feasible by supply chain automation. Additionally, this idea is implemented within the framework of supply chain management, which is the logistics concept of supply chain coordination.

Supply Chain Management is a concept that aims to create the best possible channels of communication between distributors and end users, particularly: researching customer needs and offering products that best meet them; processing orders and requests promptly; scheduling deliveries so that there is never an unmet demand for the goods; developing long-term relationships with distributors and continuously growing the sales network. The benefits of supply-chain management deployment were also discussed in the essay. It includes higher profitability, shorter order processing times and expenses, quicker market access, lower procurement costs, lower warehouse stock levels, lower production costs, and so on.

As a result of the investigation, we can conclude that supply-chain management can be implemented in the oil business to assist save costs, boost profitability, and manage supply and delivery plans.
